1. Introduction

Let $X_1, \ldots, X_n$ be independent random variables with common unknown density $f$ in $\mathbb{R}^d$. Let $\{f_1, \ldots, f_M\}$ be a finite set of functions with $f_j \in L_2(\mathbb{R}^d)$, $j = 1, \ldots, M$, called a dictionary. We consider estimators of $f$ that belong to the linear span of $\{f_1, \ldots, f_M\}$. We will be particularly interested in the case where $M \gg n$. Denote by $f_\lambda$ the linear combinations

$$f_\lambda(x) = \sum_{j=1}^M \lambda_j f_j(x), \quad \lambda = (\lambda_1, \ldots, \lambda_M) \in \mathbb{R}^M.$$ 

Let us mention some examples where such estimates are of importance.
• **Estimation in sparse mixture models.** Assume that the density \( f \) can be represented as a finite mixture \( f = f_\lambda \) where \( f_j \) are known probability densities and \( \lambda^* \) is a vector of mixture probabilities. The number \( M \) can be very large, much larger than the sample size \( n \), but we believe that the representation is sparse, i.e., that very few coordinates of \( \lambda^* \) are non-zero, with indices corresponding to a set \( I^* \subseteq \{1, \ldots, M\} \). Our goal is to estimate the weight vector \( \lambda^* \) by a vector \( \hat{\lambda} \) that adapts to this unknown sparsity and to identify \( I^* \), with high probability.

• **Adaptive nonparametric density estimation.** Assume that the density \( f \) is a smooth function, and \( \{f_1, \ldots, f_M\} \) are the first \( M \) functions from a basis in \( L_2(\mathbb{R}^d) \). If the basis is orthonormal, a natural idea is to estimate \( f \) by an orthogonal series estimator which has the form \( f_\lambda \) with \( \lambda \) having the coordinates \( \lambda_j = n^{-1} \sum_{i=1}^n f_j(X_i) \). However, it is well known that such estimators are very sensitive to the choice of \( M \), and a data-driven selection of \( M \) or thresholding is needed to achieve adaptivity (cf., e.g., [30, 21, 6]); moreover these methods have been applied with \( M \leq n \). We would like to cover more general problems where the system \( \{f_j\} \) is not necessarily orthonormal, even not necessarily a basis, \( M \) is not necessarily smaller than \( n \), but an estimate of the form \( f_\lambda \) still achieves, adaptively, the optimal rates of convergence.

• **Aggregation of density estimators.** Assume now that \( f_1, \ldots, f_M \) are some preliminary estimators of \( f \) constructed from a training sample independent of \( (X_1, \ldots, X_n) \), and we would like to aggregate \( f_1, \ldots, f_M \). This means that we would like to construct a new estimator, the aggregate, which is approximately as good as the best among \( f_1, \ldots, f_M \) or approximately as good as the best linear or convex combination of \( f_1, \ldots, f_M \). General notions of aggregation and optimal rates are introduced in [27, 33]. Aggregation of density estimators is discussed in [31, 29, 28] and more recently in [5] where one can find further references. The aggregates that we have in mind here are of the form \( f_\lambda \) with suitably chosen weights \( \hat{\lambda} = \hat{\lambda}(X_1, \ldots, X_n) \in \mathbb{R}^M \).

In this paper, we suggest a data-driven choice of \( \hat{\lambda} \) that can be used in all the examples mentioned above and also more generally. We define \( \hat{\lambda} \) as a minimizer of an \( \ell_1 \)-penalized criterion, that we call SPADES (SPArse Density EStimation). This method was introduced in [11]. The idea of \( \ell_1 \) penalized estimation is widely used in the statistical literature, mainly in linear regression where it is usually referred to as the Lasso criterion [32, 12, 15, 18, 26]. For Gaussian sequence models or for regression with orthogonal design matrix the Lasso
is equivalent to soft thresholding [14, 24]. Model selection consistency of the Lasso type linear regression estimators is treated in many papers including [26, 40, 39, 41, 25]. Recently, \(\ell_1\) penalized methods have been extended to nonparametric regression with general fixed or random design [8, 9, 10, 4], as well as to some classification and other more general prediction type models [22, 23, 35, 7].

In this paper we show that \(\ell_1\) penalized techniques can also be successfully used in density estimation. In Section 2 we give the construction of the SPADES estimates and we show that they satisfy general oracle inequalities in Section 3. In the remainder of the paper we discuss the implications of these results for two particular problems, identification of mixture components and adaptive nonparametric density estimation. For the application of SPADES in aggregation problems we refer to [11].

Section 4 is devoted to mixture models. A vast amount of literature exists on estimation in mixture models, especially when the number of components is known; see e.g. [36] for examples involving the EM algorithm. The literature on determining the number of mixture components is still developing, and we will focus on this aspect here. Recent works on the selection of the number of components (mixture complexity) are [20, 2]. A consistent selection procedure specialized to Gaussian mixtures is suggested in [20]. The method of [20] relies on comparing a nonparametric kernel density estimator with the best parametric fit of various given mixture complexities. Nonparametric estimators based on the combinatorial density method (see [13]) are studied in [2, 3]. These can be applied to estimating consistently the number of mixture components, when the components have known functional form. Both [20, 2] can become computationally infeasible when \(M\), the number of candidate components, is large. The method proposed here bridges this gap and guarantees correct identification of the mixture components with probability close to 1.

In Section 4 we begin by giving conditions under which the mixture weights can be estimated accurately, with probability close to 1. This is an intermediate result that allows us to obtain the main result of Section 4, correct identification of the mixture components. We show that in identifiable mixture models, if the mixture weights are above the noise level, then the components of the mixture can be recovered with probability larger than \(1 - \varepsilon\), for any given small \(\varepsilon\). Our results are non-asymptotic, they hold for any \(M\) and \(n\). Since the emphasis here is on correct component selection, rather than optimal density estimation, the tuning sequence that accompanies the \(\ell_1\) penalty needs to be slightly larger than the one
used for good prediction. The same phenomenon has been noted for $\ell_1$ penalized estimation in regression and generalized regression model, see, e.g., [7].

Section 5 uses the oracle inequalities of Section 3 to show that SPADES estimates adaptively achieve optimal rates of convergence (up to a logarithmic factor) simultaneously on a large scale of functional classes, such as Hölder, Sobolev or Besov classes, as well as on the classes of sparse densities, i.e., densities having only a finite, but unknown, number of non-zero wavelet coefficients.

2. Definition of SPADES

Consider the $L_2(\mathbb{R}^d)$ norm

$$\|g\| = \left(\int_{\mathbb{R}^d} g^2(x) \, dx\right)^{1/2}$$

associated with the inner product

$$\langle g, h \rangle = \int_{\mathbb{R}^d} g(x)h(x) \, dx$$

for $g, h \in L_2(\mathbb{R}^d)$. Note that if the density $f$ belongs to $L_2(\mathbb{R}^d)$ and $X$ has the same distribution as $X_i$, we have, for any $g \in L_2$,

$$\langle g, f \rangle = \mathbb{E}g(X),$$

where the expectation is taken under $f$. Moreover

$$\|f - g\|^2 = \|f\|^2 + \|g\|^2 - 2 \langle g, f \rangle = \|f\|^2 + \|g\|^2 - 2\mathbb{E}g(X). \tag{2.1}$$

In view of identity (2.1), minimizing $\|f_\lambda - f\|^2$ in $\lambda$ is the same as minimizing

$$\gamma(\lambda) = -2\mathbb{E}f_\lambda(X) + \|f_\lambda\|^2.$$

The function $\gamma(\lambda)$ depends on $f$ but can be approximated by its empirical counterpart

$$\hat{\gamma}(\lambda) = -\frac{2}{n} \sum_{i=1}^{n} f_\lambda(X_i) + \|f_\lambda\|^2.$$

This motivates the use of $\hat{\gamma} = \hat{\gamma}(\lambda)$ as the empirical criterion, see, for instance, [6, 30, 37].

We define the penalty

$$\text{pen}(\lambda) = 2 \sum_{j=1}^{M} \omega_j |\lambda_j| \tag{2.2}$$
with weights \( \omega_j \) to be specified later, and we propose the following data-driven choice of \( \lambda \):

\[
\hat{\lambda} = \arg \min_{\lambda \in \mathbb{R}^M} \{ \hat{\gamma}(\lambda) + \text{pen}(\lambda) \}
\]

\[
= \arg \min_{\lambda \in \mathbb{R}^M} \left\{ -\frac{2}{n} \sum_{i=1}^{n} f_{\lambda}(X_i) + \| f_{\lambda} \|^2 + 2 \sum_{j=1}^{M} \omega_j |\lambda_j| \right\}.
\]

Our estimator of density \( f \) that we will further call the SPADES estimator is defined by

\[
f^\wedge (x) = f_{\hat{\lambda}}(x), \quad \forall x \in \mathbb{R}^d.
\]

It is easy to see that, for an orthonormal system \( \{ f_j \} \), the SPADES estimator coincides with the soft thresholding estimator whose components are of the form \( \hat{\lambda}_j = (1 - \omega_j / |\tilde{\lambda}_j|)_{+} \tilde{\lambda}_j \) where \( \tilde{\lambda}_j = n^{-1} \sum_{i=1}^{n} f_j(X_i) \) and \( x_{+} = \max(0, x) \). We see that in this case \( \omega_j \) is the threshold for the \( j \)th component of a preliminary estimator \( \tilde{\lambda} = (\tilde{\lambda}_1, \ldots, \tilde{\lambda}_M) \).

The SPADES estimate can be easily computed by convex programming even if \( M \gg n \). It retains the desirable theoretical properties of other density estimators, the computation of which may become problematic for \( M \gg n \). We refer to [13] for a thorough overview on combinatorial methods in density estimation, to [34] for density estimation using support vector machines and to [6] for density estimates using penalties proportional to the dimension.

### 3. Oracle inequalities for SPADES

#### 3.1. Preliminaries

For any \( \lambda \in \mathbb{R}^M \), let

\[
J(\lambda) = \{ j \in \{1, \ldots, M \} : \lambda_j \neq 0 \}
\]

be the set of indices corresponding to non-zero components of \( \lambda \) and

\[
M(\lambda) = |J(\lambda)| = \sum_{j=1}^{M} I\{\lambda_j \neq 0\}
\]

its cardinality. Here \( I\{\cdot\} \) denotes the indicator function. Furthermore, set

\[
\sigma_j^2 = \text{Var}(f_j(X_1)), \quad L_j = \| f_j \|_{\infty}
\]

for \( 1 \leq j \leq M \), where \( \text{Var}(\zeta) \) denotes the variance of random variable \( \zeta \) and \( \| \cdot \|_{\infty} \) is the \( L_{\infty}(\mathbb{R}^d) \) norm.

We will prove sparsity oracle inequalities for the estimator \( \hat{\lambda} = \hat{\lambda}(\omega_1, \ldots, \omega_M) \), provided the weights \( \omega_j \) are chosen large enough. We first consider a simple choice:

\[
\omega_j = 4L_j r(\delta/2)
\]
where $0 < \delta < 1$ is a user-specified parameter and

$$
(3.2) \quad r(\delta) = r(M, n, \delta) = \sqrt{\frac{\log(M/\delta)}{n}}.
$$

The oracle inequalities that we prove below hold with a probability of at least $1 - \delta$ and are non-asymptotic: they are valid for all integers $M$ and $n$. The first of these inequalities is established under a coherence condition on the “correlations”

$$
\rho_M(i, j) = \frac{\langle f_i, f_j \rangle}{\|f_i\| \cdot \|f_j\|}, \quad i, j = 1, \ldots, M.
$$

For $\lambda \in \mathbb{R}^M$, we define a local coherence number (called maximal local coherence) by

$$
\rho(\lambda) = \max_{i \in J(\lambda)} \max_{j \neq i} |\rho_M(i, j)|,
$$

and we also define

$$
F(\lambda) = \max_{j \in J(\lambda)} \frac{\omega_j}{\|f_j\|} r(\delta/2)
$$

and

$$
G = \max_{1 \leq j \leq M} \frac{r(\delta/2) \|f_j\|}{\omega_j}.
$$

3.2. Main results.

**Theorem 1.** Assume that $L_j < \infty$ for $1 \leq j \leq M$. Then with probability at least $1 - \delta$ for all $\lambda \in \mathbb{R}^M$ that satisfy

$$
(3.3) \quad 16G F(\lambda) \rho(\lambda) M(\lambda) \leq 1
$$

and all $\alpha > 1$ and we have the following oracle inequality:

$$
\|f^\lambda - f\|^2 + \frac{\alpha}{2(\alpha - 1)} \sum_{j=1}^M \omega_j |\tilde{\lambda}_j - \lambda_j| \leq \frac{\alpha + 1}{\alpha - 1} \|f^\lambda - f\|^2 + \frac{8\alpha^2}{\alpha - 1} \{F(\lambda)G\}^2 r^2(\delta/2) M(\lambda).
$$

Note that only a condition on the local coherence (3.3) is required to obtain the result of Theorem 1. However, even this condition can be too strong, because the bound on “correlations” should be uniform over $j \in J(\lambda), i \neq j$, cf. the definition of $\rho(\lambda)$. For example, this excludes the cases where the “correlations” can be relatively large for a small number of pairs $(i, j)$ and almost zero for otherwise. To account for this situation, we suggest below another version of Theorem 1. Instead of maximal local coherence, we introduce cumulative local coherence defined by

$$
\rho_*(\lambda) = \sum_{i \in J(\lambda)} \sum_{j > i} |\rho_M(i, j)|.
$$
Theorem 2. Assume that $L_j < \infty$ for $1 \leq j \leq M$. Then with probability at least $1 - \delta$ for all $\lambda \in \mathbb{R}^M$ that satisfy
\begin{equation}
16F(\lambda) G_\rho(\lambda) \sqrt{M(\lambda)} \leq 1
\end{equation}
and all $\alpha > 1$ we have the following oracle inequality:
\begin{equation}
\| f^\dagger - f \|^2 + \frac{\alpha}{2(\alpha - 1)} \sum_{j=1}^{M} \omega_j |\widehat{\lambda}_j - \lambda_j| \leq \frac{\alpha + 1}{\alpha - 1} \| f_\lambda - f \|^2 + \frac{8\alpha^2}{\alpha - 1} \{ F(\lambda) G \}_{\rho_2}(\delta/2) M(\lambda).
\end{equation}

Theorem 2 is useful when we deal with sparse Gram matrices $\Psi_M = \langle f_i, f_j \rangle_{1 \leq i, j \leq M}$ that have only a small number $N$ of non-zero off-diagonal entries. This number will be called a sparsity index of matrix $\Psi_M$, and is defined as
\begin{equation}
N = |\{(i, j) : i, j \in \{1, \ldots, M\}, i > j \text{ and } \psi_M(i, j) \neq 0\}|,
\end{equation}
where $\psi_M(i, j)$ is the $(i, j)$th entry of $\Psi_M$ and $|A|$ denotes the cardinality of a set $A$. Clearly, $N < M(M + 1)/2$. We therefore obtain the following immediate corollary of Theorem 2.

Corollary 1. Let $\Psi_M$ be a Gram matrix with sparsity index $N$. Then the assertion of Theorem 2 holds if we replace there (3.4) by the condition
\begin{equation}
16F(\lambda) N \sqrt{M(\lambda)} \leq 1.
\end{equation}

We finally give an oracle inequality, which is valid under the assumption that the Gram matrix $\Psi_M$ is positive definite. It is simpler to use than the above results when the dictionary is orthonormal or forms a frame. Note that the coherence assumptions considered above do not necessarily imply the positive definiteness of $\Psi_M$. Vice versa, the positive definiteness of $\Psi_M$ does not imply these assumptions.

Theorem 3. Assume that $L_j < \infty$ for $1 \leq j \leq M$ and that the Gram matrix $\Psi_M$ is positive definite with minimal eigenvalue larger than or equal to $\kappa_M > 0$. Then, with probability at least $1 - \delta$, for all $\alpha > 1$ and all $\lambda \in \mathbb{R}^M$ we have
\begin{equation}
\| f^\dagger - f \|^2 + \frac{\alpha}{\alpha - 1} \sum_{j=1}^{M} \omega_j |\widehat{\lambda}_j - \lambda_j| \leq \frac{\alpha + 1}{\alpha - 1} \| f_\lambda - f \|^2 + \left( \frac{8\alpha^2}{\alpha - 1} \right) \frac{G(\lambda)}{n \kappa_M},
\end{equation}
where
\begin{equation}
G(\lambda) \triangleq \sum_{j \in J(\lambda)} \omega_j^2 = \frac{16 \log(2M/\delta)}{n} \sum_{j \in J(\lambda)} L_j^2.
\end{equation}
We can consider some other choices for $\omega_j$ without affecting the previous results. For instance,

\[
\omega_j = 2\sqrt{2}\sigma_j r(\delta/2) + \frac{8}{3}L_j r^2(\delta/2)
\]

or

\[
\omega_j = 2\sqrt{2}T_j r(\delta/2) + \frac{8}{3}L_j r^2(\delta/2)
\]

with

\[
T_j^2 = \frac{2}{n} \sum_{i=1}^{n} f_j^2(X_i) + 2L_j r^2(\delta/2).
\]

yield the same conclusions. These modifications of (3.1) prove useful, for example, for situations where $f_j$ are wavelet basis functions, cf. Section 5. The choice (3.8) of $\omega_j$ has an advantage of being completely data-driven.

**Theorem 4.** Theorems 1–3 and Corollary 1 hold with the choices (3.7) or (3.8) for the weights $\omega_j$ without changing the assertions. They also remain valid if we replace these $\omega_j$ by any $\omega'_j$ such that $\omega'_j > \omega_j$.

If $\omega_j$ is chosen as in (3.8), our bounds on the risk of SPADES estimator involve the random variables $(1/n) \sum_{i=1}^{n} f_j^2(X_i)$. These can be replaced in the bounds by deterministic values using the following lemma.

**Lemma 1.** Assume that $L_j < \infty$ for $j = 1, \ldots, M$. Then

\[
P \left( \frac{1}{n} \sum_{i=1}^{n} f_j^2(X_i) \leq 2E f_j^2(X_1) + \frac{4}{3}L_j^2 r^2(\delta/2), \forall j = 1, \ldots, M \right) \geq 1 - \delta/2.
\]

From Theorem 4 and Lemma 1 we find that, for the choice of $\omega_j$ as in (3.8), the oracle inequalities of Theorems 1–3 and Corollary 1 remain valid with probability at least $1 - 3\delta/2$ if we replace the $\omega_j$ in these inequalities by the expressions $2\sqrt{2}T_j r(\delta/2) + (8/3)L_j r^2(\delta/2)$ where $\hat{T}_j = \left(2E f_j^2(X_1) + (4/3)L_j^2 r^2(\delta/2)\right)^{1/2}$.

**3.3. Proofs.** We first prove the following preliminary lemma. Define the random variables

\[
V_j = \frac{1}{n} \sum_{i=1}^{n} \{f_j(X_i) - Ef_j(X_i)\}
\]

and the event

\[
A = \bigcap_{j=1}^{M} \{2|V_j| \leq \omega_j\}.
\]
Lemma 2. Assume that $L_j < \infty$ for $j = 1, \ldots, M$. Then for all $\lambda \in \mathbb{R}^M$ we have that, on the event $A$,

\begin{equation}
\|f^\bullet - f\|^2 + \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| \leq \|f_\lambda - f\|^2 + 4 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j|.
\end{equation}

Proof. By the definition of $\hat{\lambda}$,

\begin{equation}
-\frac{2}{n} \sum_{i=1}^{n} f_\lambda(X_i) + \|f_\lambda\|^2 + 2 \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j| \leq \frac{2}{n} \sum_{i=1}^{n} f_\lambda(X_i) + \|f_\lambda\|^2 + 2 \sum_{j=1}^{M} \omega_j |\lambda_j|
\end{equation}

for all $\lambda \in \mathbb{R}^M$. We rewrite this inequality as

\begin{equation}
\|f^\bullet - f\|^2 \leq \|f_\lambda - f\|^2 - 2 < f, f^\bullet - f_\lambda > + \frac{2}{n} \sum_{i=1}^{n} (f^\bullet - f_\lambda)(X_i) + 2 \sum_{j=1}^{M} \omega_j |\lambda_j| - 2 \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j|
\end{equation}

Then, on the event $A$,

\begin{equation}
\|f^\bullet - f\|^2 \leq \|f_\lambda - f\|^2 + \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| + 2 \sum_{j=1}^{M} \omega_j |\lambda_j| - 2 \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j|.
\end{equation}

Add $\sum_j \omega_j |\hat{\lambda}_j - \lambda_j|$ to both sides of the inequality to obtain

\begin{equation}
\|f^\bullet - f\|^2 + \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j|
\end{equation}

\begin{align*}
&\leq \|f_\lambda - f\|^2 + 2 \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| + 2 \sum_{j=1}^{M} \omega_j |\lambda_j| - 2 \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j| \\
&\leq \|f_\lambda - f\|^2 + 2 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j| + 2 \sum_{j \in J(\lambda)} \omega_j |\lambda_j| - 2 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j| \\
&\leq \|f_\lambda - f\|^2 + 4 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j|
\end{align*}

where we used that $\lambda_j = 0$ for $j \not\in J(\lambda)$ and the triangle inequality. □
For the choice (3.1) for $\omega_j$, we find by Hoeffding's inequality for sums of independent random variables $\zeta_{ij} = f_j(X_i) - E f_j(X_i)$ with $|\zeta_{ij}| \leq 2L_j$ that

$$P(A) \leq \sum_{j=1}^M P\{|V_j| > \omega_j\} \leq 2 \sum_{j=1}^M \exp \left( -\frac{2n\omega_j^2/4}{8L_j^2} \right) = \delta.$$ 

**Proof of Theorem 1.** In view of Lemma 2, we need to bound $\sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j|$. Set

$$u_j = \hat{\lambda}_j - \lambda_j, \quad U(\lambda) = \sum_{j \in J(\lambda)} |u_j||f_j||, \quad U = \sum_{j=1}^M |u_j||f_j||.$$

Then, by the definition of $F(\lambda)$ and the Cauchy-Schwarz inequality

$$\sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j| \leq rF(\lambda)U(\lambda).$$

Since

$$\sum_{i,j \notin J(\lambda)} <f_i,f_j> u_iu_j \geq 0,$$

we obtain

$$\sum_{j \in J(\lambda)} u_j^2||f_j||^2 = ||f^\bullet - f_\lambda||^2 - \sum_{i,j \notin J(\lambda)} u_iu_j <f_i,f_j>$$

$$+ 2 \sum_{i \notin J(\lambda)} \sum_{j \in J(\lambda)} u_iu_j <f_i,f_j> - \sum_{i,j \in J(\lambda), i \neq j} u_iu_j <f_i,f_j>$$

$$\leq ||f^\bullet - f_\lambda||^2 + 2\rho(\lambda) \sum_{i \notin J(\lambda)} |u_i||f_i|| \sum_{j \in J(\lambda)} |u_j||f_j||$$

$$+ \rho(\lambda) \sum_{i,j \in J(\lambda)} |u_i||u_j||f_i||f_j||$$

$$= ||f^\bullet - f_\lambda||^2 + 2\rho(\lambda)U(\lambda)U - \rho(\lambda)U^2(\lambda).$$

The left-hand side can be bounded by $\sum_{j \in J(\lambda)} u_j^2||f_j||^2 \geq U^2(\lambda)/M(\lambda)$ using the Cauchy-Schwarz inequality, and we obtain that

$$U^2(\lambda) \leq ||f^\bullet - f_\lambda||^2 M(\lambda) + 2\rho(\lambda)M(\lambda)U(\lambda)U,$$

which immediately implies

$$U(\lambda) \leq 2\rho(\lambda)M(\lambda)U + \sqrt{M(\lambda)}||f^\bullet - f_\lambda||.$$
Hence, by Lemma 2, we have with probability at least $1 - \delta$,

$$\|f^\bullet - f\|^2 + \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| \leq \|f_\lambda - f\|^2 + 4 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j|$$

$$\leq \|f_\lambda - f\|^2 + 4rF(\lambda)U(\lambda)$$

$$\leq \|f_\lambda - f\|^2 + 4rF(\lambda) \left\{ 2\rho(\lambda)M(\lambda)U + \sqrt{M(\lambda)} \|f^\bullet - f_\lambda\| \right\}$$

$$\leq \|f_\lambda - f\|^2 + 8F(\lambda)\rho(\lambda)M(\lambda)\sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| + 4rF(\lambda)\sqrt{M(\lambda)} \|f^\bullet - f_\lambda\|,$$

where $r = r(\delta/2)$. For all $\lambda \in \mathbb{R}^M$ that satisfy relation (3.3), we find that with probability exceeding $1 - \delta$,

$$\|f^\bullet - f\|^2 + \frac{1}{2} \sum_{j=1}^{M} \omega_j |\hat{\lambda}_j - \lambda_j| \leq \|f_\lambda - f\|^2 + 4rF(\lambda)G\sqrt{M(\lambda)} \|f^\bullet - f_\lambda\|$$

$$\leq \|f_\lambda - f\|^2 + 2 \left\{ 2rGF(\lambda)\sqrt{M(\lambda)} \right\} \|f^\bullet - f\| + 2 \left\{ 2rGF(\lambda)\sqrt{M(\lambda)} \right\} \|f_\lambda - f\|.$$

After applying the inequality $2xy \leq x^2/\alpha + \alpha y^2$ ($x, y \in \mathbb{R}, \alpha > 0$) for each of the last two summands, we easily find the claim. \hfill \Box

**Proof of Theorem 2.** The proof is similar to that of Theorem 1. With

$$U_*(\lambda) = \sqrt{\sum_{j \in J(\lambda)} u_j^2 \|f_j\|^2}$$

we obtain now the following analogue of (3.12):

$$U_*^2(\lambda) \leq \|f^\bullet - f_\lambda\|^2 + 2\rho_*(\lambda) \max_{i \in J(\lambda), j > i} |u_i||f_i||u_j||f_j|$$

$$\leq \|f^\bullet - f_\lambda\|^2 + 2\rho_*(\lambda) \sum_{j=1}^{M} |u_j||f_j|$$

$$= \|f^\bullet - f_\lambda\|^2 + 2\rho_*(\lambda) U_*(\lambda) U.$$

Hence, as in the proof of Theorem 1, we have

$$U_*(\lambda) \leq 2\rho_*(\lambda) U + \|f^\bullet - f_\lambda\|,$$
and using the inequality \( U_*(\lambda) \geq U(\lambda)/\sqrt{M(\lambda)} \) we find

\[
(3.14) \quad U(\lambda) \leq 2\rho_*(\lambda)\sqrt{M(\lambda)}U + \sqrt{M(\lambda)}\|f^\bullet - f_\lambda\|.
\]

Note that (3.14) differs from (3.13) only in the fact that the factor \( 2\rho(\lambda)M(\lambda) \) on the right hand side is now replaced by \( 2\rho_*(\lambda)\sqrt{M(\lambda)} \). Up to this modification, the rest of the proof is identical to that of Theorem 1.

\[\Box\]

Proof of Theorem 3. By the assumption on \( \Psi_M \) we have

\[
\|f_\lambda\|^2 = \sum_{i,j} \lambda_i \lambda_j \int_{\mathbb{R}^d} f_i(x)f_j(x)\,dx \geq \kappa_M \sum_{j \in J(\lambda)} \lambda_j^2.
\]

By the Cauchy-Schwarz inequality, we find

\[
4 \sum_{j \in J(\lambda)} \omega_j |\hat{\lambda}_j - \lambda_j| \leq 4 \left( \sum_{j \in J(\lambda)} \omega_j^2 \right)^{1/2} \left( \sum_{j \in J(\lambda)} |\hat{\lambda}_j - \lambda_j|^2 \right)^{1/2} \leq 4 \left( \frac{\sum_{j \in J(\lambda)} \omega_j^2}{n\kappa_M} \right)^{1/2} \|f^\bullet - f_\lambda\|.
\]

Combination with Lemma 2 yields that, with probability at least \( 1 - \delta \),

\[
(3.15) \quad \|f^\bullet - f\|^2 + \sum_{j=1}^M \omega_j |\hat{\lambda}_j - \lambda_j| \leq \|f_\lambda - f\|^2 + 4 \left( \frac{\sum_{j \in J(\lambda)} \omega_j^2}{n\kappa_M} \right)^{1/2} \|f^\bullet - f_\lambda\| \leq \|f_\lambda - f\|^2 + b \left( \|f^\bullet - f\| + \|f_\lambda - f\| \right)
\]

where \( b = 4\sqrt{\sum_{j \in J(\lambda)} \omega_j^2 / n\kappa_M} \). Applying the inequality \( 2xy \leq x^2/\alpha + y^2 \) \((x, y \in \mathbb{R}, \alpha > 0)\) for each of the last two summands in (3.15) we get the result. \[\Box\]

Proof of Theorem 4. Write \( \bar{\omega}_j = 2\sqrt{2\sigma_j}r(\delta/2) + (8/3)L_j r^2(\delta/2) \) for the choice of \( \omega_j \) in (3.7). Using Bernstein’s exponential inequality for sums of independent random variables \( \zeta_{ij} = f_j(X_i) - \mathbb{E}f_j(X_i) \) with \( |\zeta_{ij}| \leq 2L_j \), we obtain that

\[
(3.16) \quad \mathbb{P}(A^c) = \mathbb{P} \left( \bigcup_{j=1}^M \{2|V_j| > \bar{\omega}_j\} \right) \leq \sum_{j=1}^M \mathbb{P}\{2|V_j| > \bar{\omega}_j\} \leq \sum_{j=1}^M \exp \left( - \frac{n\bar{\omega}_j^2/4}{2\text{Var}(f_j(X_1)) + 2L_j \bar{\omega}_j/3} \right) \leq M \exp(-nr^2(\delta/2)) = \delta/2.
\]
Let now \( \omega_j \) be defined by (3.8). Then, using (3.16), we can write

\[
\mathbb{P}(A^c) = \mathbb{P}\left( \bigcup_{j=1}^{M} \{2|V_j| > \omega_j\} \right)
\]

\[
\leq \sum_{j=1}^{M} \mathbb{P}\{2|V_j| > \bar{\omega}_j\} + \sum_{j=1}^{M} \mathbb{P}\{\bar{\omega}_j > \omega_j\}
\]

\[
\leq \frac{\delta}{2} + \sum_{j=1}^{M} \mathbb{P}\{\bar{\omega}_j > \omega_j\}.
\]

Define

\[
t_j = 2 \frac{\mathbb{E}f_j^4(X_1) \log(2M/\delta)}{\mathbb{E}f_j^2(X_1)} n
\]

and note that

\[
\frac{2}{n} \sum_{i=1}^{n} f_j^2(X_i) + t_j \leq T_j^2.
\]

Then

\[
\mathbb{P}\{\bar{\omega}_j > \omega_j\} = \mathbb{P}\{\text{Var}(f_j(X_1)) > T_j^2\}
\]

\[
\leq \mathbb{P}\{\mathbb{E}f_j^2(X_1) > \frac{2}{n} \sum_{i=1}^{n} f_j^2(X_i) + t_j\}
\]

\[
\leq \exp \left( -\frac{n\{\mathbb{E}f_j^2(X_1) + t_j\}^2}{8\mathbb{E}f_j^4(X_1)} \right)
\]

using Proposition 2.6 in [38]

\[
\leq \exp \left( -\frac{nt_j\mathbb{E}f_j^2(X_1)}{2\mathbb{E}f_j^4(X_1)} \right)
\]

since \((x + y)^2 \geq 4xy\)

which is less than \(\delta/(2M)\). Plugging this in (3.17) concludes the proof. \(\square\)
Proof of Lemma 1. Using Bernstein’s exponential inequality for sums of independent random variables $f_j^2(X_i) - E f_j^2(X_1)$ and the fact that $E f_j^2(X_1) \leq L_j^2 E f_j^2(X_1)$ we find

$$\begin{align*}
\mathbb{P}\left(\frac{1}{n} n \sum_{i=1}^n f_j^2(X_i) &\geq 2E f_j^2(X_1) + \frac{4}{3}L_j^2 r^2(\delta/2) \right) \\
&= \mathbb{P}\left(\frac{1}{n} n \sum_{i=1}^n f_j^2(X_i) - E f_j^2(X_1) \geq E f_j^2(X_1) + \frac{4}{3}L_j^2 r^2(\delta/2) \right) \\
&\leq \exp\left(-\frac{n(E f_j^2(X_1) + \frac{4}{3}L_j^2 r^2(\delta/2))^2}{2E f_j^2(X_1) + \frac{4}{3}L_j^2 (E f_j^2(X_1) + \frac{4}{3}L_j^2 r^2(\delta/2))}\right) \\
&\leq \exp(-nr^2(\delta/2)) = \frac{\delta}{2M},
\end{align*}$$

which implies the lemma. \qed

4. Sparse estimation in mixture models

In this section we assume that the true density $f$ can be represented as a finite mixture

$$f(x) = \sum_{j \in I^*} \lambda_j^* f_j(x),$$

where $I^* \subseteq \{1, \ldots, M\}$ is unknown, $f_j$ are known probability densities and $\lambda_j^* \neq 0$ for all $j \in I^*$. The focus of this section is on model selection, i.e., on the correct identification of the set $I^*$. We set $\lambda^* = (\lambda_1^*, \ldots, \lambda_M^*)$ where $\lambda_j^* = 0, j \notin I^*$.

For clarity of exposition we consider a simplified version of the general set-up introduced above. We compute the estimates of $\lambda^*$ via (2.3), with weights defined by (cf. (3.1)):

$$\omega_j = 4Lr, \quad \text{for all } j,$$

where $r > 0$ is a constant that we specify below, and for clarity of exposition we replaced all $L_j = \|f_j\|_{\infty}$ by an upper bound $L$ on $\max_{1 \leq j \leq M} L_j$. We assume that all $f_j$ have been standardized to have $\|f_j\| = 1$. Note that under these assumptions condition (3.3) takes the form

$$(4.1) \quad \rho(\lambda) \leq \frac{1}{16M(\lambda)}.$$  

We state (4.1) for the true vector $\lambda^*$ in the following form.

Condition (A).

$$\rho^* \leq \frac{1}{16k^*}$$

where $k^* = |I^*| = M(\lambda^*)$ and $\rho^* = \rho(\lambda^*)$. 

The results of Section 3 are valid for any $r$ larger or equal to $r(\delta/2) = \{\log(2M/\delta)/n\}^{1/2}$. They give bounds on the predictive performance of SPADES. As noted in, e.g., [7], for $\ell_1$-penalized model selection in regression, the tuning sequence $\omega_j$ required for correct selection is typically larger than the one that yields good prediction. We show below that the same is true for selecting the components of a mixture of densities. Specifically, in this section we will take the value

$$r = r(M, n, \delta/(2M)) = \sqrt{\log(2M^2/\delta)/n}.$$  \hspace{1cm} (4.2)

We will use the following corollary of Theorem 1, obtained for $\alpha = \sqrt{2}$.

**Corollary 2.** Assume that Condition (A) holds. Then with probability at least $1 - \delta/M$ we have

$$\sum_{j=1}^{M} |\hat{\lambda}_j - \lambda_j| \leq \frac{4\sqrt{2}}{L} k^* \sqrt{\log(2M^2/\delta)/n}.$$ \hspace{1cm}  (4.3)

Inequality (4.3) guarantees that the estimate $\hat{\lambda}$ is close to the true $\lambda^*$ in $\ell_1$ norm, if the number of mixture components $k^*$ is substantially smaller than $\sqrt{n}$. We regard this as an intermediate step for the next result that deals with the identification of $I^*$.

### 4.1. Correct identification of the mixture components.

We now show that $I^*$ can be identified with probability close to 1 by our procedure. Let $\hat{I} = J(\hat{\lambda})$ be the set of indices of the non-zero components of $\hat{\lambda}$ given by (2.3). In what follows we investigate when $P(\hat{I} = I^*) \geq 1 - \varepsilon$ for a given $0 < \varepsilon < 1$. Our results are non-asymptotic, they hold for any fixed $M$ and $n$.

We need two conditions to ensure that correct recovery of $I^*$ is possible. The first one is the identifiability of the model, as quantified by Condition (A) above. The second condition requires that the weights of the mixture are above the noise level, quantified by $r$. We state it as follows.

**Condition (B).**

$$\min_{j \in I^*} |\lambda_j^*| > 4(\sqrt{2} + 1)rL$$

where $L = \max \left(1/\sqrt{3}, \max_{1 \leq j \leq M} L_j \right)$ and $r$ is given in (4.2).

**Theorem 5.** Let $0 < \delta < 1/2$ be a given number. Assume that Conditions (A) and (B) hold. Then $P(\hat{I} = I^*) \geq 1 - 2\delta(1 + 1/M)$. 

Proof. We begin by noticing that
\[
P(\hat{I} \neq I^*) \leq P(I^* \not\subseteq \hat{I}) + P(\hat{I} \not\subseteq I^*),
\]
and we control each of the probabilities on the right hand side separately.

**Control of** \(P(I^* \not\subseteq \hat{I})\). By the definitions of the sets \(\hat{I}\) and \(I^*\) we have
\[
P(I^* \not\subseteq \hat{I}) \leq P(\hat{\lambda}_k = 0 \text{ for some } k \in I^*) \leq k^* \max_{k \in I^*} P(\hat{\lambda}_k = 0).
\]
We control the last probability by using the characterization (5.9) of \(\hat{\lambda}\) given in Lemma 3 of the Appendix. We also recall that \(E f_k(X_1) = \sum_{j \in I^*} \lambda_j^* \langle f_k, f_j \rangle = \sum_{j=1}^M \lambda_j^* \langle f_k, f_j \rangle\), since we assumed that the density of \(X_1\) is the mixture \(f^* = \sum_{j \in I^*} \lambda_j^* f_j\). We therefore obtain, for \(k \in I^*\),
\[
P(\hat{\lambda}_k = 0) = P \left( \frac{1}{n} \sum_{i=1}^n f_k(X_i) - \sum_{j=1}^M \hat{\lambda}_j \langle f_j, f_k \rangle \leq 4rL; \hat{\lambda}_k = 0 \right)
\]
\[
= P \left( \frac{1}{n} \sum_{i=1}^n f_k(X_i) - E f_k(X_1) - \sum_{j=1}^M (\hat{\lambda}_j - \lambda_j^*) \langle f_j, f_k \rangle \leq 4rL; \hat{\lambda}_k = 0 \right)
\]
\[
\leq P \left( \lambda_k^* \| f_k \|^2 + \frac{1}{n} \sum_{i=1}^n f_k(X_i) - E f_k(X_1) - \sum_{j \neq k} (\hat{\lambda}_j - \lambda_j^*) \langle f_j, f_k \rangle \leq 4rL \right)
\]
\[
(4.4) \leq P \left( \frac{1}{n} \sum_{i=1}^n f_k(X_i) - E f_k(X_1) \geq \frac{|\lambda_k^*| \| f_k \|^2}{2} - 2rL \right)
\]
\[
+ P \left( \sum_{j \neq k} (\hat{\lambda}_j - \lambda_j^*) \langle f_j, f_k \rangle \geq \frac{|\lambda_k^*| \| f_k \|^2}{2} - 2rL \right).
\]

To bound (4.4) we use Hoeffding’s inequality, as in the course of Lemma 2. We first recall that \(\| f_k \| = 1\) for all \(k\) and that, by Condition (B), \(\min_{k \in I^*} |\lambda_k^*| \geq 4(\sqrt{2} + 1)Lr\), with \(r = r(\delta/(2M)) = \{\log(2M^2/\delta)/n\}^{1/2}\). Therefore
\[
(4.6) \leq P \left( \frac{1}{n} \sum_{i=1}^n f_k(X_i) - E f_k(X_1) \geq \frac{|\lambda_k^*|}{2} - 2rL \right)
\]
\[
\leq P \left( \frac{1}{n} \sum_{i=1}^n f_k(X_i) - E f_k(X_1) \geq 2\sqrt{2}rL \right) \leq \frac{\delta}{M^2}.
\]
To bound (4.5) notice that, by Conditions (A) and (B),
\[
\mathbb{P} \left( \left| \sum_{j \neq k} (\hat{\lambda}_j - \lambda_j^*) \langle f_j, f_k \rangle \right| \geq \frac{|\lambda_k^*|}{2} - 2rL \right) \\
\leq \mathbb{P} \left( \sum_{j=1}^{M} |\hat{\lambda}_j - \lambda_j^*| \geq 32\sqrt{2rLk^*} \right) \\
\leq \mathbb{P} \left( \sum_{j=1}^{M} |\hat{\lambda}_j - \lambda_j^*| \geq \frac{4\sqrt{2rLk^*}}{L} \right) \leq \frac{\delta}{M},
\]
where the penultimate inequality holds since, by definition, $L^2 \geq 1/3$ and the last inequality holds by Corollary 4.

Combining the above results we obtain
\[
\mathbb{P}(I^* \not\subseteq \hat{I}) \leq k^* \frac{\delta}{M^2} + k^* \frac{\delta}{M} \leq \frac{\delta}{M} + \delta.
\]

**Control of $\mathbb{P}(\hat{I} \not\subseteq I^*)$.** Let

\[
(4.7) \quad h(\mu) = -\frac{2}{n} \sum_{i=1}^{n} \sum_{j \in I^*} \mu_j f_j(X_i) + \| \sum_{j \in I^*} \mu_j f_j \|^2 + 8rL \sum_{j \in I^*} |\mu_j|.
\]
Let

\[
(4.8) \quad \tilde{\mu} = \arg \min_{\mu \in \mathbb{R}^{k^*}} h(\mu).
\]
Consider the random event

\[
(4.9) \quad \mathcal{B} = \bigcap_{k \not\in I^*} \left\{ -\frac{1}{n} \sum_{i=1}^{n} f_k(X_i) + \sum_{j \in I^*} \tilde{\mu}_j \langle f_j, f_k \rangle \leq 4Lr \right\}.
\]
Let $\hat{\mu} \in \mathbb{R}^M$ be the vector that has the components of $\tilde{\mu}$ given by (4.8) in positions corresponding to the index set $I^*$ and zero components elsewhere. By the first part of Lemma 3 in the Appendix we have that $\hat{\mu} \in \mathbb{R}^M$ is a solution of (2.3) on the event $\mathcal{B}$. Recall that $\hat{\lambda}$ is a also solution of (2.3). By the definition of the set $\hat{I}$ we have that $\hat{\lambda}_k \neq 0$ for $k \in \hat{I}$. By construction, $\tilde{\mu}_k \neq 0$ for some subset $S \subseteq I^*$. By the second part of Lemma 3 in the Appendix, any two solutions have non-zero elements in the same positions. Therefore $\hat{I} = S \subseteq I^*$ on $\mathcal{B}$. 
Thus,

\begin{equation}
\mathbb{P}(\hat{I} \not\subseteq I^*) \leq \mathbb{P}(B^c)
\end{equation}

\begin{align*}
\leq \sum_{k \notin I^*} \mathbb{P} \left\{ \left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) + \sum_{j \in I^*} \bar{\mu}_j \langle f_j, f_k \rangle \right| \geq 4rL \right\} \\
\leq \sum_{k \notin I^*} \mathbb{P} \left( \left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - Ef_k(X_1) \right| \geq 2\sqrt{2}rL \right) \\
+ \sum_{k \notin I^*} \mathbb{P} \left( \sum_{j \in I^*} |\bar{\mu}_j - \lambda^*_j| \langle f_j, f_k \rangle \geq (4 - 2\sqrt{2})rL \right).
\end{align*}

Reasoning as in (4.6) above we find

\begin{equation*}
\sum_{k \notin I^*} \mathbb{P} \left( \left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - Ef_k(X_1) \right| \geq 2\sqrt{2}rL \right) \leq \frac{\delta}{M}.
\end{equation*}

To bound the last sum in (4.10) we first notice that Theorem 1 (if we replace there \(r(\delta/2)\) by the larger value \(r(\delta/(2M))\), cf. Theorem 4) applies to \(\bar{\mu}\) given by (4.8). In particular

\begin{equation*}
\mathbb{P} \left( \sum_{j \in I^*} |\bar{\mu}_j - \lambda^*_j| \langle f_j, f_k \rangle \geq 4\sqrt{2}Lk^*r \right) \leq \frac{\delta}{M}.
\end{equation*}

Therefore, by Condition (A), we have

\begin{align*}
\sum_{k \notin I^*} \mathbb{P} \left( \sum_{j \in I^*} |\bar{\mu}_j - \lambda^*_j| \langle f_j, f_k \rangle \geq (4 - 2\sqrt{2})rL \right) \\
\leq \sum_{k \notin I^*} \mathbb{P} \left( \sum_{j \in I^*} |\bar{\mu}_j - \lambda^*_j| \geq 32(4 - 2\sqrt{2})k^*rL \right) \\
\leq \sum_{k \notin I^*} \mathbb{P} \left( \sum_{j \in I^*} |\bar{\mu}_j - \lambda^*_j| \geq \frac{4\sqrt{2}}{L}k^*r \right) \leq \delta,
\end{align*}

which holds since \(L^2 \geq 1/3\). Collecting all the bounds above we obtain

\begin{equation*}
\mathbb{P}(\hat{I} \neq I^*) \leq 2\delta + \frac{2\delta}{M},
\end{equation*}

which concludes the proof. ■

4.2. Example: Identifying true components in mixtures of Gaussian densities.
Consider an ensemble of \(M\) Gaussian densities \(f_j\)'s in \(\mathbb{R}^d\) with means \(\mu_j\) and covariance matrices \(\tau_j \mathbb{I}_d\), where \(\mathbb{I}_d\) is the unit \(d \times d\) matrix. In what follows we show that Condition
(A) holds if the means of the Gaussian densities are well separated and we make this precise below. Therefore, in this case, Theorem 5 guarantees that if the weights of the mixture are above the threshold given in Condition B, we can recover the true mixture components with high probability via our procedure.

Recall that Condition (A) requires

$$\rho^* = \max_{i \in I^*, j \neq i} \frac{\langle f_i, f_j \rangle}{\|f_i\| \|f_j\|} \leq \frac{1}{16k^*}.$$ 

The densities are

$$f_j(x) = \frac{1}{\sqrt{2\pi \tau_j}} \exp \left( -\frac{\|x - \mu_j\|^2}{2\tau_j^2} \right),$$

where \( \| \cdot \|_2 \) denotes the Euclidean norm. Let \( \tau_{\text{max}} = \max_{1 \leq j \leq M} \tau_j \) and \( D_{\text{min}}^2 = \min_{k \neq j} \| \mu_k - \mu_j \|^2_2 \). Via simple algebra we obtain

$$\rho^* \leq \exp \left( -\frac{D_{\text{min}}^2}{4\tau_{\text{max}}^2} \right).$$

Therefore, Condition (A) holds if

$$D_{\text{min}}^2 \geq 4\tau_{\text{max}}^2 \log(16k^*).$$

Using this and Theorem 5 we see that SPADES can identifies the true components in a mixture of Gaussian densities if the square Euclidean distance between any two means is large enough as compared to the largest variance of the components in the mixture.

Note that Condition (B) on the size of the mixture weights involves the constant \( L \), which in this example can be taken as

$$L = \max \left( \frac{1}{\sqrt{3}}, \max_{1 \leq j \leq M} \| f_j \|_\infty \right) = \max \left( \frac{1}{\sqrt{3}}, \frac{1}{(\sqrt{2\pi \tau_{\text{min}}})^d} \right),$$

where \( \tau_{\text{min}} = \min_{1 \leq j \leq M} \tau_j \).

5. SPADES for Adaptive Nonparametric Density Estimation

We assume in this section that the density \( f \) is defined on a bounded interval of \( \mathbb{R} \) that we take without loss of generality to be the interval \([0, 1]\). Consider a countable system of functions \( \{ \psi_{lk}, l \geq -1, k \in V(l) \} \) in \( L_2 \), where the set of indices \( V(l) \) satisfies \( |V(-1)| \leq C \), \( 2^l \leq |V(l)| \leq C2^l \), \( l \geq 0 \), for some constant \( C \), and where the functions \( \psi_{lk} \) satisfy

$$\| \psi_{lk} \| \leq C_1, \quad \| \psi_{lk} \|_\infty \leq C_1 2^{l/2}, \quad \left\| \sum_{k \in V(l)} \psi_{lk}^2 \right\|_\infty \leq C_1 2^l,$$
for all $l \geq -1$ and for some $C_1 < \infty$. Examples of such systems $\{\psi_{lk}\}$ are given, for instance, by compactly supported wavelet bases, see, e.g., [19]. In this case $\psi_{lk}(x) = 2^{l/2}(2^l x - k)$ for some compactly supported function $\psi$. We assume that $\{\psi_{lk}\}$ is a frame, i.e., there exist positive constants $c_1$ and $c_2$ depending only on $\{\psi_{lk}\}$ such that, for any two sequences of coefficients $\beta_{lk}, \beta'_{lk}$,

$$c_1 \sum_{l=-1}^{\infty} \sum_{k \in V(l)} (\beta_{lk} - \beta'_{lk})^2 \leq \left\| \sum_{l=-1}^{\infty} \sum_{k \in V(l)} (\beta_{lk} - \beta'_{lk}) \psi_{lk} \right\|^2 \leq c_2 \sum_{l=-1}^{\infty} \sum_{k \in V(l)} (\beta_{lk} - \beta'_{lk})^2. \tag{5.2}$$

If $\{\psi_{lk}\}$ is an orthonormal wavelet basis, this condition is satisfied with $c_1 = c_2 = 1$.

Now, choose $\{f_1, \ldots, f_M\} = \{\psi_{lk}, -1 \leq l \leq l_{\max}, k \in V(l)\}$ where $l_{\max}$ is such that $2^{l_{\max}} \approx n/(\log n)$. Then also $M \approx n/(\log n)$. The coefficients $\lambda_j$ are now indexed by $j = (l,k)$, and we set by definition $\lambda_{(l,k)} = 0$ for $(l,k) \notin \{-1 \leq l \leq l_{\max}, k \in V(l)\}$. Assume that there exist coefficients $\beta^*_l$ such that

$$f = \sum_{l=-1}^{\infty} \sum_{k \in V(l)} \beta^*_l \psi_{lk}$$

where the series converges in $L_2$. Then Theorem 3 easily implies the following result.

**Theorem 6.** Let $f_1, \ldots, f_M$ be as defined above with $M \approx n/(\log n)$, and let $\omega_j$ be given by (3.8) for $\delta = n^{-2}$. Then for all $n \geq 1$, $\lambda \in \mathbb{R}^M$ we have with probability at least $1 - n^{-2}$,

$$\|f^\bullet - f\|^2 \leq K \left( \sum_{l=-1}^{\infty} \sum_{k \in V(l)} (\lambda_{(l,k)} - \beta^*_l)^2 \right) + \sum_{(l,k) \in J(\lambda)} \left[ \frac{1}{n} \sum_{i=1}^{n} \psi^\lambda_{lk}(X_i) \frac{\log n}{n} + 2\left( \frac{\log n}{n} \right)^2 \right]$$

where $K$ is a constant independent of $f$.}

This is a general oracle inequality that allows one to show that the estimator $f^\bullet$ attains minimax rates of convergence, up to a logarithmic factor simultaneously on various functional classes. We will explain this in detail for the case where $f$ belongs to a class of functions $\mathcal{F}$ satisfying the following assumption for some $s > 0$.

**Condition (C).** For any $f \in \mathcal{F}$ and any $l' \geq 0$ there exists a sequence of coefficients $\lambda = \{\lambda_{(l,k)}, -1 \leq l \leq l', k \in V(l)\}$ such that

$$\sum_{l=-1}^{\infty} \sum_{k \in V(l)} (\lambda_{(l,k)} - \beta^*_l)^2 \leq C_2 2^{-2l's} \tag{5.4}$$
for a constant $C_2$ independent of $f$.

It is well known that Condition (C) holds for various functional classes $\mathcal{F}$, such as Hölder, Sobolev, Besov classes, if $\{\psi_{lk}\}$ is an appropriately chosen wavelet basis, see, e.g., [19] and the references cited therein. In this case $s$ is the smoothness parameter of the class. Moreover, the basis $\{\psi_{lk}\}$ can be chosen so that Condition (C) is satisfied with $C_2$ independent of $s$ for all $s \leq s_{\text{max}}$, where $s_{\text{max}}$ is a given positive number. This allows for adaptation in $s$.

Under Condition (C) we obtain from (5.3) that, with probability at least $1 - n^{-2}$,

$$\|f^\frown - f\|^2 \leq \min_{l' \leq l_{\text{max}}} K \left( C_2 2^{-2l's} + \sum_{(l,k): l \leq l'} \left[ \frac{1}{n} \sum_{i=1}^{n} \psi_{lk}(X_i) \frac{\log n}{n} + 2^l \left( \frac{\log n}{n} \right)^2 \right] \right)$$

From (5.5) and the last inequality in (5.1) we find for some constant $K'$, with probability at least $1 - n^{-2}$,

$$\|f^\frown - f\|^2 \leq \min_{l' \leq l_{\text{max}}} K' \left( 2^{-2l's} + 2^{l'} \left( \frac{\log n}{n} \right) + 2^{2l'} \left( \frac{\log n}{n} \right)^2 \right)$$

$$= O \left( \left( \frac{\log n}{n} \right)^{-2s/(2s+1)} \right)$$

where the last expression is obtained by choosing $l'$ such that $2^{l'} \asymp (n/\log n)^{1/(2s+1)}$. It follows from (5.6) that $f^\frown$ converges with the optimal rate (up to a logarithmic factor) simultaneously on all the functional classes satisfying Condition (C). Note that the definition of the functional class is not used in the construction of the estimator $f^\frown$, so this estimator is optimal adaptive in the rate of convergence (up to a logarithmic factor) on this scale of functional classes for $s \leq s_{\text{max}}$. Results of such type, and even more pointed (without extra logarithmic factors in the rate and sometimes with exact asymptotic minimax constants) are known for various other adaptive density estimators, see, for instance, [16, 6, 19, 21, 28, 29] and the references cited therein. These papers consider classes of densities that are uniformly bounded by a fixed constant, see the recent discussion in [5]. This prohibits, for example, free scale transformations of densities within a class. Inequality (5.6) does not have this drawback. It allows to get the rates of convergence for classes of unbounded densities $f$ as well.

Another example is given by the classes of sparse densities defined as follows:

$$\mathcal{L}_0(m) = \left\{ f : [0, 1] \to \mathbb{R} : f \text{ is a probability density and } \left| \{ j : \langle f, f_j \rangle \neq 0 \} \right| \leq m \right\}$$

where $m \leq M$ is an unknown integer. If $f_1, \ldots, f_M$ is a wavelet system as defined above and $J^* = \{ j = (l,k) : \langle f, f_j \rangle \neq 0 \}$, then under the conditions of Theorem 6 for any $f \in \mathcal{L}_0(m)$
we have, with probability at least $1 - n^{-2}$,

$$
\|f^\ast - f\|^2 \leq K \left( \sum_{(l,k) \in J^*} \left[ \frac{1}{n} \sum_{i=1}^{n} \psi_{lk}^2(X_i) \frac{\log n}{n} + 2^{l} \left( \frac{\log n}{n} \right)^2 \right] \right).
$$

From (5.7), using Lemma 1 and the first two inequalities in (5.1) we obtain the following result.

**Corollary 3.** Let the assumptions of Theorem 6 hold. Then, for every $L < \infty$ and $n \geq 1$,

$$
\sup_{f \in \mathcal{L}_0(m) \cap \{f : \|f\|_{\infty} \leq L\}} \mathbb{P}\left\{ \|f^\ast - f\|^2 \geq b \left( \frac{m \log n}{n} \right) \right\} \leq \left( \frac{3}{2} \right) n^{-2}, \quad \forall \ m \leq M,
$$

where $b > 0$ is a constant depending only on $L$.

Corollary 3 can be viewed as an analogue for density estimation of the adaptive minimax results for $\mathcal{L}_0$ classes obtained in the Gaussian sequence model [1, 17] and in the random design regression model [10].

**Appendix**

**Lemma 3.** (I) Let $\tilde{\mu}$ be given by (4.8). Then $\tilde{\mu} = (\tilde{\mu}, 0) \in \mathbb{R}^M$ is a minimizer in $\lambda \in \mathbb{R}^M$ of

$$
g(\lambda) = -\frac{2}{n} \sum_{i=1}^{n} f_k(X_i) + \|f_\lambda\|^2 + 8Lr \sum_{k=1}^{M} |\lambda_k|.
$$

on the random event $\mathcal{B}$ defined in (4.9).

(II) Any two minimizers of $g(\lambda)$ have non-zero components in the same positions.

**Proof.** (I). Since $g$ is convex, by standard results in convex analysis, $\tilde{\lambda} \in \mathbb{R}^M$ is a minimizer of $g$ if and only if $0 \in D_{\tilde{\lambda}}$ where $D_{\tilde{\lambda}}$ is the subdifferential of $g(\lambda)$:

$$
D_{\tilde{\lambda}} = \{w \in \mathbb{R}^M : w_k = -\frac{2}{n} \sum_{i=1}^{n} f_k(X_i) + 2 \sum_{j=1}^{M} \lambda_j \langle f_j, f_k \rangle + 8rv_k, v_k \in V_k(\lambda_k), 1 \leq k \leq M \}
$$

where

$$
V_k(\lambda_k) = \begin{cases} 
\{L\} & \text{if } \lambda_k > 0, \\
\{-L\} & \text{if } \lambda_k < 0, \\
[-L, L] & \text{if } \lambda_k = 0.
\end{cases}
$$
Therefore, \( \bar{\lambda} \) minimizes \( g(\cdot) \) if and only if, for all \( 1 \leq k \leq M \),

\[
\frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j=1}^{M} \bar{\lambda}_j \langle f_j, f_k \rangle = 4Lr \text{sign}(\bar{\lambda}_k), \quad \text{if } \bar{\lambda}_k \neq 0, \tag{5.9}
\]

\[
\left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j=1}^{M} \bar{\lambda}_j \langle f_j, f_k \rangle \right| \leq 4Lr, \quad \text{if } \bar{\lambda}_k = 0. \tag{5.10}
\]

We now show that \( \bar{\mu} = (\tilde{\mu}, 0) \in \mathbb{R}^M \) with \( \tilde{\mu} \) given in (4.8) satisfies (5.9)–(5.10) on the event \( B \) and therefore is a minimizer of \( g(\lambda) \) on this event. Indeed, since \( \tilde{\mu} \) is a minimizer of the convex function \( h(\mu) \) given in (4.7), the same convex analysis argument as above implies that

\[
\frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j \in I^*} \tilde{\mu}_j \langle f_j, f_k \rangle = 4rL \text{sign}(\tilde{\mu}_k), \quad \text{if } \tilde{\mu}_k \neq 0, \quad k \in I^*,
\]

\[
\left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j \in I^*} \tilde{\mu}_j \langle f_j, f_k \rangle \right| \leq 4rL, \quad \text{if } \tilde{\mu}_k = 0, \quad k \in I^*.
\]

Note that on the event \( B \) we also have

\[
\left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j \in I^*} \tilde{\mu}_j \langle f_j, f_k \rangle \right| \leq 4rL, \quad \text{if } k \notin I^* \quad \text{(for which } \tilde{\mu}_k = 0, \text{ by construction)}.
\]

Here \( \tilde{\mu}_k \) denotes the \( k \)th coordinate of \( \tilde{\mu} \). The above three displays and the fact that \( \tilde{\mu}_k = \tilde{\mu}_k, k \in I^* \), show that \( \tilde{\mu} \) satisfies conditions (5.9)–(5.10) and is therefore a minimizer of \( g(\lambda) \) on the event \( B \).

(II). We now prove the second assertion of the lemma. In view of (5.9) the index set \( S \) of the non-zero components of any minimizer \( \bar{\lambda} \) of \( g(\lambda) \) satisfies

\[
S = \left\{ k \in \{1, \ldots, M\} : \left| \frac{1}{n} \sum_{i=1}^{n} f_k(X_i) - \sum_{j=1}^{M} \bar{\lambda}_j \langle f_j, f_k \rangle \right| = 4rL \right\}.
\]

Therefore, if for any two minimizers \( \bar{\lambda}^{(1)} \) and \( \bar{\lambda}^{(2)} \) of \( g(\lambda) \) we have

\[
\sum_{j=1}^{M} (\tilde{\lambda}_j^{(1)} - \tilde{\lambda}_j^{(2)}) \langle f_j, f_k \rangle = 0, \quad \text{for all } k,
\]

then \( S \) is the same for all minimizers of \( g(\lambda) \).

Thus, it remains to show (5.11). We use simple properties of convex functions. First, we recall that the set of minima of a convex function is convex. Then, if \( \tilde{\lambda}^{(1)} \) and \( \tilde{\lambda}^{(2)} \) are two distinct points of minima, so is \( \rho \tilde{\lambda}^{(1)} + (1 - \rho) \tilde{\lambda}^{(2)} \), for any \( 0 < \rho < 1 \). Re-write this convex combination as \( \tilde{\lambda}^{(2)} + \rho \eta \), where \( \eta = \tilde{\lambda}^{(1)} - \tilde{\lambda}^{(2)} \). Recall that the minimum value of any convex
function is unique. Therefore, for any $0 < \rho < 1$, the value of $g(\lambda)$ at $\lambda = \bar{\lambda}^2 + \rho \eta$ is equal to some constant $C$:

$$F(\rho) \triangleq -\frac{2}{n} \sum_{i=1}^{n} \sum_{j=1}^{M} \left( \bar{\lambda}_j^{(2)} + \rho \eta_j \right) f_j(X_i) + \int \left( \sum_{j=1}^{M} \left( \bar{\lambda}_j^{(2)} + \rho \eta_j \right) f_j(x) \right)^2 dx$$

$$+ 8rL \sum_{j=1}^{M} \left| \bar{\lambda}_j^{(2)} + \rho \eta_j \right| = C.$$  

By taking the derivative with respect to $\rho$ of $F(\rho)$ we obtain that, for all $0 < \rho < 1$,

$$F' (\rho) = -\frac{2}{n} \sum_{i=1}^{n} \sum_{j=1}^{M} \eta_j f_j(X_i) + 8rL \sum_{j=1}^{M} \eta_j \text{sign}(\bar{\lambda}_j^{(2)} + \rho \eta_j)$$

$$+ 2 \int \left( \sum_{j=1}^{M} \left( \bar{\lambda}_j^{(2)} + \rho \eta_j \right) f_j(x) \right) \left( \sum_{j=1}^{M} \eta_j f_j(x) \right) dx = 0.$$  

By continuity of $\rho \mapsto \bar{\lambda}_j^{(2)} + \rho \eta_j$, there exists an open interval in $(0, 1)$ on which $\rho \mapsto \text{sign}(\bar{\lambda}_j^{(2)} + \rho \eta_j)$ is constant for all $j$. Therefore, on that interval,

$$F'(\rho) = 2\rho \int \left( \sum_{j=1}^{M} \eta_j f_j(x) \right)^2 dx + C'$$

where $C'$ does not depend on $\rho$. This is compatible with $F'(\rho) = 0$, $\forall 0 < \rho < 1$, (cf. (5.12)) only if

$$\sum_{j=1}^{M} \eta_j f_j(x) = 0, \text{ for all } x,$$

and therefore

$$\sum_{j=1}^{M} \eta_j \langle f_j, f_k \rangle = 0, \text{ for all } k \in \{1, \ldots, M\},$$

which is the desired result. This completes the proof of the lemma. \qed
